

## Energy & Respiration

A-Level Biology ■ Topic 12

A-Level Biology

Energy & Respiration

### What we will cover

- 1 ATP – the energy currency
- 2 Substrates & RQ
- 3 The four stages
- 4 Glycolysis
- 5 Krebs & oxidative phosphorylation
- 6 Anaerobic respiration

*muscles need energy*

# 1

## ATP and substrates

Energy & Respiration

↳ ATP and substrates

### ATP – the energy currency

**ATP** 三磷酸腺苷 stores energy in its terminal phosphate bond. Hydrolysis to ADP + P<sub>i</sub> releases a small, usable amount; respiration (and photosynthesis) rebuilds it. It works as a currency because it is **small and soluble**, so it moves easily around the cell, and because it is **easily made and re-made**, again and again. The energy pays for **active transport** 主动运输 against a gradient and for **anabolic** 合成代谢 reactions – building large molecules such as in DNA replication and protein synthesis.

ATP is a short-term, mobile energy currency – not a store. Cells make it as they need it.

Energy & Respiration

↳ ATP and substrates

### Substrates and RQ

**Respiratory quotient** 呼吸商  $RQ = \text{CO}_2 \text{ produced} / \text{O}_2 \text{ used}$ . Carbohydrate  $\approx 1.0$ ; lipid  $\approx 0.7$ ; protein  $\approx 0.9$ . An RQ above 1 suggests anaerobic respiration as well.

# 2

## Aerobic respiration

Energy & Respiration

Aerobic respiration

The four stages

■ glycolysis 糖酵解 – in the cytoplasm 细胞质

■ link reaction 连接反应 & Krebs cycle 克雷布斯循环 – the matrix 基质

■ oxidative phosphorylation 氧化磷酸化 – the inner membrane

Reduced NAD & FAD carry hydrogen to the membrane.

glucose

glycolysis

pyruvate

link reaction

Krebs cycle

oxidative phosphorylation

lots of ATP + H<sub>2</sub>O

CO<sub>2</sub> out

CO<sub>2</sub> out

reduced NAD, FAD

cytoplasm

matrix

matrix

inner membrane (cristae)

Energy & Respiration

Aerobic respiration

Glycolysis

Glucose 葡萄糖 (6C) is split into two pyruvate 丙酮酸 (3C).

It spends 2 ATP but makes 4 – a net 2 ATP (plus reduced NAD) – and needs no oxygen.

Energy & Respiration

Aerobic respiration

Glycolysis, in detail

glucose (6C)

use 2 ATP

fructose biphosphate (6C)

split

2 × triose phosphate (3C)

make 4 ATP, reduce NAD

2 × pyruvate (3C)

net gain: 2 ATP + 2 reduced NAD

Glycolysis spends 2 ATP to start but makes 4, so the net gain is 2 ATP (plus reduced NAD) – and it needs no oxygen

Energy & Respiration

Aerobic respiration

Krebs cycle

oxaloacetate (4C)

+ acetyl CoA (2C)

citrate (6C)

CO<sub>2</sub> out reduced NAD

5-carbon

4-carbon

reduced NAD, FAD; ATP

Krebs cycle

The link reaction makes acetyl CoA 乙酰辅酶 A, which joins the cycle. Each turn:

■ decarboxylation 脱羧 – releases CO<sub>2</sub>

■ dehydrogenation 脱氢 – reduces NAD & FAD

Energy & Respiration

Aerobic respiration

The link reaction and the Krebs cycle

the link reaction

pyruvate enters the mitochondrion, loses a carbon dioxide 二氧化碳, and is joined to coenzyme A 辅酶 A

the product

acetyl coenzyme A – two carbons, entering the cycle

the cycle starts

acetyl CoA joins oxaloacetate 草酰乙酸 (4C) to form citrate 柠檬酸 (6C)

decarboxylation 脱羧

removes carbon as carbon dioxide – twice per turn

dehydrogenation

removes hydrogen onto the coenzymes 辅酶 NAD and FAD

per turn

2 CO<sub>2</sub>, 3 NADH, 1 FADH<sub>2</sub>, 1 ATP – and the cycle turns twice per glucose

A redox indicator 指示剂 such as DCPIP or methylene blue loses its colour as it gains hydrogen from respiring cells. The faster it decolourises, the faster respiration is.

Energy & Respiration

Aerobic respiration

Oxidative phosphorylation

Makes most of the ATP:

■ electrons pass the electron transport chain 电子传递链, pumping protons

■ protons flow back through ATP synthase ATP 合酶 (chemiosmosis 化学渗透)

■ oxygen 氧气 is the final electron acceptor → water

## Oxidative phosphorylation, in detail

Electrons pump protons ( $H^+$ ) into the intermembrane space; they flow back through ATP synthase to make ATP (chemiosmosis)

# 3 Anaerobic respiration

## Anaerobic respiration

Without oxygen, only glycolysis runs. **Fermentation** 发酵 regenerates NAD:

- mammals  $\rightarrow$  **lactate** 乳酸
- yeast 酵母  $\rightarrow$  **ethanol** 乙醇 +  $CO_2$

Far less ATP than aerobic respiration.

## Anaerobic respiration, in detail

this regenerates NAD so glycolysis can keep running (far less ATP than aerobic)

Without oxygen, only glycolysis runs.

## Rice and waterlogged roots

A root of a plant that grows in water, seen in cross-section. The big white gaps are the aerenchyma – connected air channels that let oxygen diffuse all the way down to roots sitting in oxygen-poor mud

## ATP – the energy currency, continued

Respiration adds a phosphate to make ATP; the cell breaks it off again to release energy

## How ATP is made, and what RQ tells you

|                                     |                                                                                           |
|-------------------------------------|-------------------------------------------------------------------------------------------|
| <b>phosphorylation 磷酸化</b>          | direct transfer of a phosphate group to ADP – substrate-level phosphorylation             |
| <b>chemiosmosis 化学渗透</b>            | protons pumped across a membrane flow back through ATP synthase, which makes the ATP      |
| <b>the respiratory quotient 呼吸商</b> | $RQ = \frac{\text{CO}_2 \text{ produced}}{\text{O}_2 \text{ used}}$                       |
| <b>the values</b>                   | carbohydrate 1.0, protein about 0.9, lipid about 0.7                                      |
| <b>why lipid is lowest</b>          | it is the most reduced substrate, so it needs the most oxygen per carbon                  |
| <b>above 1.0</b>                    | means some respiration is <b>anaerobic</b> – CO <sub>2</sub> released with no oxygen used |

RQ identifies the **substrate** being respired. Measuring it on **germinating 萌发 seeds** or **invertebrates 无脊椎动物** in a respirometer is the standard practical.

## Respiratory substrates and RQ

Lipids release the most energy per gram, then proteins, then carbohydrates

## The structure of mitochondria

Two real mitochondria, photographed with an electron microscope. The dark stripes crossing the inside are the cristae – all that folding is what makes the surface for the electron transport chain so large

## Respiratory substrates and RQ, continued

The soda lime absorbs the CO<sub>2</sub> given off, so the gas volume falls only by the oxygen used – and the bead moves in by that amount

## Exam tips

- State **where** each stage happens and its ATP yield: glycolysis (cytoplasm), link reaction + Krebs (matrix), oxidative phosphorylation (inner membrane, most ATP).
- Explain the roles of **NAD/FAD** (carry hydrogen to the electron transport chain) and of oxygen (the final electron acceptor).
- RQ** = CO<sub>2</sub> produced ÷ O<sub>2</sub> used (≈ 1.0 carbohydrate, 0.7 lipid); know how a respirometer measures it.
- Anaerobic respiration gives lactate (animals) or ethanol + CO<sub>2</sub> (yeast/plants) and far less ATP (glycolysis only).

# 4 Recap

## Worked example – respiratory quotient

Find the RQ for aerobic respiration of glucose:  $\text{C}_6\text{H}_{12}\text{O}_6 + 6\text{O}_2 \rightarrow 6\text{CO}_2 + 6\text{H}_2\text{O}$ .

- $\text{RQ} = \frac{\text{CO}_2 \text{ produced}}{\text{O}_2 \text{ used}}$
- $= \frac{6}{6} = 1.0$
- Lipids are less oxidised, so they need **more** oxygen  $\Rightarrow \text{RQ} \approx 0.7$ .
- An RQ **above 1.0** means some **anaerobic** respiration is also happening.

RQ identifies the **sub-  
strate**: carbohydrate 1.0,  
protein  $\approx 0.9$ , lipid  $\approx 0.7$ .  
Above 1.0  $\Rightarrow$  extra  $\text{CO}_2$   
from anaerobic respiration.

## Topic 12 – key takeaways

### 1 ATP

the cell's energy currency;  $\text{ADP} + \text{P}_i$

### 2 Glycolysis

glucose to pyruvate; net 2 ATP, no  $\text{O}_2$

### 3 Krebs cycle

decarboxylation & dehydrogenation

### 4 Chemiosmosis

ATP synthase makes most ATP;  $\text{O}_2$  accepts  $\text{e}^-$

## Check yourself

- 1 Where in the cell does glycolysis happen?
- 2 What is the net ATP gain from glycolysis?
- 3 What is the final electron acceptor?
- 4 What does yeast make in anaerobic respiration?

A ribose P P P

**Answers** 1. the cytoplasm 2. 2 ATP 3. oxygen 4. ethanol and  $\text{CO}_2$
