

3.1 Electronegativity and bonding

Name: _____ Class: _____ Date: _____

Total: 9 marks

KEY WORDS electronegativity 电负性 • electron 电子 • ion 离子 • shielding 屏蔽 • atomic radius 原子半径

Objective

Build the skills to answer exam questions on **electronegativity and bonding** — defining **electronegativity** 电负性, its trends, and using **Pauling** 鲍林 values to predict bond type.

You must be able to:

- define electronegativity and explain the factors that affect it
- state and explain the trends across a period and down a group
- use electronegativity differences to predict ionic or covalent bonding

1 Worked examples

■ Electronegativity and its trends

Electronegativity is the power of an atom to attract the **electrons** in a bond towards itself. It depends on **nuclear charge** (more → higher), **atomic radius** (smaller → higher) and **shielding** (more → lower).

Electronegativity rises across a period and falls down a group — fluorine is the most electronegative

Electronegativity sets where a bond sits on the ionic-covalent scale

■ Predicting bond type

A **large** difference in Pauling values $\rightarrow$ **ionic**; a **small** difference $\rightarrow$ **covalent**.

2 Practice

2.1 Define **electronegativity**. [1]

2.2 State the most electronegative element. [1]

3 Exam-style questions

3.1 Electronegativity increases across Period 3 because: [1]

- A the atomic radius increases
 - B the nuclear charge increases while shielding stays similar
 - C more shells are added
 - D the atoms gain electrons
-

3.2 Two elements have a **large** difference in electronegativity. The bond between them is likely to be: [1]

- A metallic
 - B ionic
 - C pure covalent
 - D a hydrogen bond
-

3.3 Explain why electronegativity decreases down Group 17. [3]

3.4 Using electronegativity, explain why the bond in HCl is polar. [2]

Solutions

2.1 the power of an atom to attract the electrons in a bond towards itself.

2.2 fluorine.

3.1 B. Rising nuclear charge with similar shielding pulls bonding electrons more strongly.

3.2 B. A large electronegativity difference gives an ionic bond.

3.3 down the group each element has more shells, so a larger atomic radius and more shielding; the nucleus attracts the bonding electrons less strongly, so electronegativity falls.

3.4 chlorine is more electronegative than hydrogen, so it pulls the bonding electrons closer, giving Cl a $\delta-$ and H a $\delta+$ — a polar bond.
