## The vocabulary of a function question

**Composition of functions**  $fg(x)$  means do  $g$  first: the **composition of functions** 复合函数, and the order matters.

**Increasing and decreasing** An **increasing function** 增函数 has  $f'(x) > 0$  throughout an interval; a **decreasing function** 减函数 has  $f'(x) < 0$ .

**Identity** An **identity** 恒等式 is true for every value of  $x$  – unlike an equation, which is true for some.

**Coefficients** The **coefficients** 系数 are the numbers multiplying each power; a **quadratic inequality** 二次不等式 is solved from the sketch, not by dividing through.

An inverse exists only for a one-one function – which is why a domain is so often restricted before an inverse is asked for.

## Finding an inverse

To find  $f^{-1}$ : write  $y = f(x)$ , make  $x$  the subject, then swap the letters.

The domain of  $f$  decides which square root you keep.

$f(x) = (x+3)^2 - 12$  for  $x \geq 0$ . Find  $f^{-1}$ .

$(x+3)^2 = y+12 \Rightarrow x+3 = \sqrt{y+12}$ , taking the **positive** root because  $x \geq 0$  means  $x+3 \geq 3 > 0$ .

$$f^{-1}(x) = \sqrt{x+12} - 3.$$

# 2 Coordinate geometry

## Coordinate geometry

Line gradient  $m = \frac{y_2 - y_1}{x_2 - x_1}$ ;  
perpendicular  $\Rightarrow m_1 m_2 = -1$ .

$$(x-a)^2 + (y-b)^2 = r^2.$$

A **tangent** 切线 meets the **radius** 半径 at a right angle.

## Straight lines

The **gradient** 斜率 through  $(x_1, y_1)$  and  $(x_2, y_2)$ :

$$m = \frac{y_2 - y_1}{x_2 - x_1}.$$

Three forms of the same line:

$$y = mx + c, \quad y - y_1 = m(x - x_1), \quad ax + by + c = 0.$$

**Parallel** 平行: equal gradients.  
**Perpendicular** 垂直: the gradients multiply to  $-1$ .

## Circles

Centre  $(a, b)$ , radius  $r$ :

$$(x-a)^2 + (y-b)^2 = r^2.$$

An expanded form such as  $x^2 + y^2 - 6x + 10y - 27 = 0$  is the **same circle** – complete the square in  $x$  and in  $y$  to read off the centre and radius.

A **tangent** 切线 meets the radius at a **right angle**. That one fact solves most circle problems.

# 3

## Circular measure and trigonometry

Pure Mathematics 1  
Circular measure and trigonometry

### Circular measure

**Radians** 弧度:  $\pi = 180^\circ$ . For a sector 扇形 (angle in radians):

$$s = r\theta, \quad A = \frac{1}{2}r^2\theta.$$

**Segment** 弓形  $= \frac{1}{2}r^2(\theta - \sin \theta)$ .

### Radians, circles, and the trigonometric words

#### Degrees and radians

$180^\circ = \pi$  radians. Every calculus formula for a trigonometric function assumes radians, never degrees 度.

#### Circle parts

The **diameter** 直径 is twice the radius; a **chord** 弦 joins two points on the circumference; arc length is  $r\theta$  and sector area  $\frac{1}{2}r^2\theta$ , with  $\theta$  in radians.

#### The functions

**Cosine** 余弦 and the **tangent function** 正切函数 join sine as the three ratios – and the tangent is undefined where the cosine is zero.

#### Principal value

An inverse trigonometric function returns only the **principal value** 主值; the other solutions come from the graph or the CAST diagram.

The **equation of a straight line** 直线方程  $y - y_1 = m(x - x_1)$  and  $\tan \theta = m$  connect this topic to coordinate geometry.

Pure Mathematics 1  
Circular measure and trigonometry

### Trigonometry

$\sin, \cos$  repeat every  $360^\circ$ ; learn exact values.

**Identities** 恒等式:  $\tan \theta \equiv \frac{\sin \theta}{\cos \theta}$ ,  $\sin^2 \theta + \cos^2 \theta \equiv 1$ .

Reduce to one function, then solve in the interval.

Pure Mathematics 1  
Circular measure and trigonometry

### Solving trigonometric equations

**Solve**  $6 \sin \theta = 1 + \frac{2}{\sin \theta}$  for  $-180^\circ < \theta < 180^\circ$ .

Multiply by  $\sin \theta$  – it is a **quadratic** in  $\sin \theta$ :

$$6 \sin^2 \theta - \sin \theta - 2 = 0 \Rightarrow (3 \sin \theta - 2)(2 \sin \theta + 1) = 0.$$

$$\sin \theta = \frac{2}{3} \Rightarrow \theta = 41.8^\circ, 138.2^\circ; \quad \sin \theta = -\frac{1}{2} \Rightarrow \theta = -30^\circ, -150^\circ.$$

Reduce to **one** function first, then find **every** solution in the interval – the marks are lost by stopping at the first one.

## The sum to infinity, in detail

The bars shrink to zero while the running sum approaches  $a/(1-r)$

# 5 Calculus

Pure Mathematics 1  
Calculus

## Differentiation

$$\frac{d}{dx} x^n = nx^{n-1}; \text{ chain: } f'(g) g'$$

**Stationary point** 驻点:  $\frac{dy}{dx} = 0$ . Then  $f'' > 0$  min,  $f'' < 0$  max.

Pure Mathematics 1  
Calculus

## Differentiation, in detail

At a **stationary point** the tangent is horizontal. The second derivative then tells you which:  $f'' > 0$  is a minimum,  $f'' < 0$  a maximum.

Pure Mathematics 1  
Calculus

## The rules of differentiation

$$\frac{d}{dx} (x^n) = nx^{n-1}$$

**Chain rule.**  $\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx}$  **Product rule.**  $(uv)' = u'v + uv'$  **Quotient rule.**  $\left(\frac{u}{v}\right)' = \frac{u'v - uv'}{v^2}$

Read the function's **shape** first:  
a power, a function of a function,  
a product, or a quotient.  
The shape names the rule.

Pure Mathematics 1  
Calculus

## Integration

Reverse of **differentiation** 微分 (+C):

$$\int (ax + b)^n dx = \frac{(ax + b)^{n+1}}{a(n+1)} + C.$$

$$\text{Area} = \int_p^q y dx.$$

## Integration, in detail

A definite integral is the **signed area** between the curve and the x-axis – area below the axis counts as negative.

## Definite integrals and area

$$\int_a^b f(x) dx = [F(x)]_a^b = F(b) - F(a),$$

the area between the curve and the x-axis from  $x = a$  to  $x = b$ . Between two curves, integrate the **difference** – upper minus lower.

Area **below** the axis integrates to a **negative** number. If a question asks for an area that crosses the axis, split the integral at the crossing.

## Using the derivative, and improper integrals

**a rate of change 变化率** a derivative *is* one – and **linked rates** use the chain rule:  $\frac{dV}{dt} = \frac{dV}{dr} \times \frac{dr}{dt}$

**stationary points** where  $\frac{dy}{dx} = 0$ ; the second derivative's sign classifies them

**increasing / decreasing** where the derivative is positive / negative

**tangent and normal** gradients  $m$  and  $-\frac{1}{m}$  at the same point

**an improper integral 广义积分** has an **infinite limit**, or an endpoint where the integrand is undefined

**how to handle it** replace the offending limit with a variable, integrate, then **take the limit**

For a linked rate, write down which quantity you know the rate of and which you want, then **chain the derivatives between them**. That sentence is most of the mark.

## What the derivative tells you about the shape

**Gradient of a curve**  $f'(x)$  is the **gradient of a curve** 曲线的梯度 at a point – the gradient of the tangent there, as a **chord** 弦 shortens to nothing.

**Maximum and minimum** At a **maximum point** 极大值点  $f' = 0$  and  $f'' < 0$ ; at a **minimum point** 极小值点  $f' = 0$  and  $f'' > 0$ .

**Point of inflexion** A **point of inflexion** 拐点 is where the curvature changes sign. A stationary one has  $f' = 0$  and  $f'' = 0$  – but  $f' = 0$  alone is not enough.

**Integration** Reversing the process needs the **constant of integration** 积分常数: one condition fixes it, and without it the answer is a family of curves.

Test a stationary point with the second derivative *or* with the sign of  $f'$  either side. Both are accepted; neither may be skipped.

## Volume of revolution

Rotate a **region** 区域 about the x-axis – each slice is a disc of area  $\pi y^2$ :

$$V = \pi \int_p^q y^2 dx.$$

## Worked example – completing the square

**Write**  $9x^2 - 36x + 8$  **as**  $p(x + q)^2 + r$ .

Take out 9 from the first two terms, complete the square inside:

$$\begin{aligned} 9(x^2 - 4x) + 8 &= 9((x - 2)^2 - 4) + 8 \\ &= 9(x - 2)^2 - 28 \end{aligned}$$

Factor out the  $x^2$  coefficient **before** completing the square. The form gives the minimum instantly:  $(2, -28)$ .

## The completed square hands you the vertex

The completed square hands you the vertex: least value  $-28$  at  $x$  equals  $2$

## Worked example – a maximum by differentiation

$y = 4x^{1/2} - x$  has a maximum at  $x = a$ .  
Find  $a$ .

$$\frac{dy}{dx} = 2x^{-1/2} - 1 = 0 \Rightarrow x^{1/2} = 2$$

$$\text{so } a = 4 \text{ (and } y = 4 \cdot 2 - 4 = 4\text{)}$$

Rewrite roots as **powers**  
( $\sqrt{x} = x^{1/2}$ ) before differentiating. Set  $dy/dx = 0$  for a turning point.

## The discriminant

The sign of  $b^2 - 4ac$  decides how many times the parabola meets the  $x$ -axis.

## Solving quadratic equations and inequalities

Three ways to solve  $ax^2 + bx + c = 0$ :  
factorise, complete the square, or

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

For an **inequality** 二次不等式, find the roots first, then decide which side of each root makes the statement true.

Sketch the **parabola** 抛物线: it is **above** the  $x$ -axis **outside** the roots and **below** it **between** them. So  $(k-4)(k-16) > 0$  gives  $k < 4$  or  $k > 16$ .

## Simultaneous equations, and quadratics in disguise

**One linear, one quadratic.** Rearrange the **linear** one for a letter, substitute into the quadratic, and you are left with a single quadratic to solve.

**Quadratic in disguise.**  $x^4 - 5x^2 + 4 = 0$  is quadratic in  $x^2$ : let  $u = x^2$ , solve  $u^2 - 5u + 4 = 0$ , then go back to  $x$ .

The same trick returns in trigonometry, with  $\sin \theta$  in place of  $u$ .

## Radians

one **radian**: the angle whose arc is exactly one radius long  
 $\pi \text{ rad} = 180^\circ$ , so  $1 \text{ rad} \approx 57.3^\circ$

degrees  $\rightarrow$  radians:  $\times \frac{\pi}{180}$  radians  $\rightarrow$  degrees:  $\times \frac{180}{\pi}$

One radian: the angle whose arc equals the radius

## Graphs of inverses and transformations

$f(x) + a$  moves up ·  $f(x + a)$  moves left ·  $af(x)$  stretch  $y$  ·  $f(ax)$  compress  $x$  if  $a > 1$

Adding to the output or input slides the curve; a multiplier stretches it.

## The transformations, and stating them fully

|                             |                                                                               |
|-----------------------------|-------------------------------------------------------------------------------|
| $y = f(x) + a$              | translation up by $a$                                                         |
| $y = f(x + a)$              | translation left by $a$ – the opposite of the sign                            |
| $y = af(x)$                 | stretch parallel to the $y$ -axis, scale factor $a$                           |
| $y = f(ax)$                 | stretch parallel to the $x$ -axis, scale factor $\frac{1}{a}$                 |
| $y = -f(x)$ and $y = f(-x)$ | reflection in the $x$ -axis, and in the $y$ -axis                             |
| combining two               | the order can matter – so state each one fully: type, direction and magnitude |

An inverse function's graph is the reflection of  $f$  in the line  $y = x$ , which is why a function must be one-to-one before an inverse exists.

## Trigonometry, continued

A Ferris wheel: a point on the rim rises and falls like a sine curve.

## The exact values, and the progressions

|                  |                                                                                                             |
|------------------|-------------------------------------------------------------------------------------------------------------|
| sin              | $\sin 30^\circ = \frac{1}{2}$ , $\sin 45^\circ = \frac{1}{\sqrt{2}}$ , $\sin 60^\circ = \frac{\sqrt{3}}{2}$ |
| cos              | $\cos 30^\circ = \frac{\sqrt{3}}{2}$ , $\cos 45^\circ = \frac{1}{\sqrt{2}}$ , $\cos 60^\circ = \frac{1}{2}$ |
| tan              | $\tan 30^\circ = \frac{1}{\sqrt{3}}$ , $\tan 45^\circ = 1$ , $\tan 60^\circ = \sqrt{3}$                     |
| a progression 數列 | a list of terms following a rule                                                                            |
| arithmetic 等差數列  | a common difference $d$ : $u_n = a + (n - 1)d$ , and $S_n = \frac{n}{2}(2a + (n - 1)d)$                     |
| geometric 等比數列   | a common ratio $r$ : $u_n = ar^{n-1}$ , and $S_\infty = \frac{a}{1 - r}$ when $ r  < 1$                     |

The exact values come from the half-equilateral triangle and the half-square. Reconstructing them from those two triangles beats memorising twelve fractions.

## Exam tips

- Show **every line of algebra** – method marks are lost by jumping steps; use the **discriminant**  $b^2 - 4ac$  to decide the number of real roots.
- Work in **radians** for circular measure ( $\text{arc} = r\theta$ , sector area  $= \frac{1}{2}r^2\theta$ ) and for calculus of trig functions.
- For **differentiation**, set  $\frac{dy}{dx} = 0$  for stationary points and use the second derivative to classify them.
- For **integration**, add  $+c$  to an indefinite integral and use limits for area; an area below the axis gives a negative integral.

# 6 Recap

## Topic 1 – key takeaways

### 1 Quadratics

discriminant decides the roots

### 2 Geometry

$m_1 m_2 = -1$ ; tangent  $\perp$  radius

### 3 Trig

$\sin^2 + \cos^2 = 1$ ; sectors in radians

### 4 Calculus

$\frac{dy}{dx} = 0$  stationary;  $\int y dx$  area

## Check yourself

- 1 How many roots if  $b^2 - 4ac < 0$ ?
- 2 Reflect a graph in which line to get its inverse?
- 3 Arc length of a sector (radians)?
- 4 Test for a minimum stationary point?

**Answers** 1. none 2.  $y = x$  3.  $s = r\theta$  4.  $f'(x) > 0$
