

**Question 9** (Answer: **C**)

- Momentum is conserved whenever no external resultant force acts – that is what isolated means.
- It holds for elastic and inelastic collisions alike, so the type of collision is irrelevant.
- A is too broad: friction or another external force can act during a collision.

**Question 10** (Answer: **D**)

- For an elastic collision the relative speed of separation equals the approach speed,  $9.0 \text{ m s}^{-1}$ .
- Momentum gives  $m(9.0) = mv'_1 + 2mv'_2$ .
- Solving the pair gives  $v'_2 = 6.0 \text{ m s}^{-1}$ , with the first object rebounding at  $-3.0 \text{ m s}^{-1}$ .

**Question 9** (Answer: **D**)

- The principle states that the total momentum of an isolated system does not change.
- A is too narrow – momentum is conserved in inelastic collisions too.
- B is the definition of momentum and C is Newton's second law.

**Question 10** (Answer: **B**)

- Resolve: the  $4.0 \text{ N s}$  is  $(+4.0, 0)$  and the  $8.0 \text{ N s}$  at  $45^\circ$  up-left is  $(-5.7, +5.7)$ .
- Adding gives  $(-1.7, +5.7) \text{ N s}$  – about  $5.9 \text{ N s}$ , mostly upwards and slightly to the left.
- Momentum is conserved, so the combined momentum after the collision is that same vector.

**Question 12** (Answer: **D**)

- In an elastic collision the relative speed of separation equals the relative speed of approach.
- After the collision the blocks separate at  $70 + 20 = 90 \text{ cm s}^{-1}$ .
- Only D approaches at  $60 + 30 = 90 \text{ cm s}^{-1}$ ; in C the blocks are already moving apart.

**Question 10** (Answer: **D**)

- They stick together, so momentum gives  $v = (2.0 \times 3.0)/3.0 = 2.0 \text{ m s}^{-1}$ .
- Before:  $\frac{1}{2}(2.0)(3.0)^2 = 9.0 \text{ J}$ . After:  $\frac{1}{2}(3.0)(2.0)^2 = 6.0 \text{ J}$ .
- The kinetic energy lost is  $9.0 - 6.0 = 3.0 \text{ J}$ .

**Question 11** (Answer: **B**)

- For an elastic collision the relative speed of approach \*equals\* the relative speed of separation.
- Written as speeds both are positive, so their sum cannot be zero – their difference is.
- A, C and D are all correct statements about the collision.

**Question 9** (Answer: **B**)

- An elastic collision is defined by the total kinetic energy being conserved.
- "Total velocity" is not a conserved quantity at all – momentum is.
- So the row reads yes for kinetic energy and no for velocity.

**Question 10** (Answer: **C**)

- In an elastic collision the total kinetic energy is unchanged, not reduced.
- A reduction in kinetic energy is exactly what makes a collision inelastic.
- A, B and D are all true of an elastic collision.

**Question 9** (Answer: **C**)

- Momentum:  $0.30(1.2) - 0.60(1.8) = -0.72 \text{ kg m s}^{-1}$ , taking P's direction as positive.
- Elastic, so the relative speed of separation equals the approach speed,  $1.2 + 1.8 = 3.0 \text{ m s}^{-1}$ .
- Solving the two together gives P at  $2.8 \text{ m s}^{-1}$  and Q at  $0.2 \text{ m s}^{-1}$ .
